IMPORTANCE Functional neurological disorders (FND) are common sources of disability in medicine. Patients have often been misdiagnosed, correctly diagnosed after lengthy delays, and/or subjected to poorly delivered diagnoses that prevent diagnostic understanding and lead to inappropriate treatments, iatrogenic harm, unnecessary and costly evaluations, and poor outcomes.

OBSERVATIONS Functional Neurological Symptom Disorder/Conversion Disorder was adopted by the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition*, replacing the term *psychogenic* with *functional* and removing the criterion of psychological stress as a prerequisite for FND. A diagnosis can now be made in an inclusionary manner by identifying neurological signs that are specific to FNDs without reliance on presence or absence of psychological stressors or suggestive historical clues. The new model highlights a wider range of past sensitizing events, such as physical trauma, medical illness, or physiological/psychophysiological events. In this model, strong ideas and expectations about these events correlate with abnormal predictions of sensory data and body-focused attention. Neurobiological abnormalities include hypoactivation of the supplementary motor area and relative disconnection with areas that select or inhibit movements and are associated with a sense of agency. Promising evidence has accumulated for the benefit of specific physical rehabilitation and psychological interventions alone or in combination, but clinical trial evidence remains limited.

CONCLUSIONS AND RELEVANCE Functional neurological disorders are a neglected but potentially reversible source of disability. Further research is needed to determine the dose and duration of various interventions, the value of combination treatments and multidisciplinary therapy, and the therapeutic modality best suited for each patient.

Functional neurological disorders (FND) are among the most common causes of neurological disability.¹ These conditions have had a long and difficult history of mind-body dualism and have now reached better-defined pathophysiological and neurobiological bases that challenge old assumptions of psychological abnormalities as their sole cause (in other words, their status as a psychogenic illness). The term *functional*, adopted by the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5)* as the primary descriptor in the term *functional neurological symptom disorder*, provides causative neutrality and may also increase patient understanding and acceptance.^{2,3} The term *conversion disorder* has been retained in the *DSM-5* from previous *DSM* iterations as an alternative expression that acknowledges unconscious processes in patients (but is used less often in neurology because of its implicit inference of

causative psychological stressors, which are not always present or may not be readily identifiable).⁴

The term *dissociative*, which is used in the *International Classification of Diseases, Tenth Revision*, implies compartmentalization or detachment of neurological functioning from normal awareness. Seizures in the context of FNDs are termed *psychogenic* and/or *nonepileptic seizures* (and often abbreviated to PNES or NES) or, less commonly, *nonepileptic attack disorder* or *dissociative seizures*. These terms have replaced the term *pseudoseizures*, which could imply feigned symptoms. Functional neurological disorders are distinct from symptoms that are intentionally produced, as in malingering and factitious disorder. Although there are no tests currently capable of demonstrating whether symptoms are willfully produced, and there may not be a clear categorical difference between voluntary and involuntary symptoms,

intentionally produced symptoms are relatively rare and will not be considered further here.

Epidemiology of FND

Functional neurological disorders have an incidence of 4 to 12 per 100 000 population per year (4 to 5 per 100 000 population per year for motor FND; 1.5 to 4.9 per 100 000 per year for video electroencephalography–confirmed cases of PNES)⁵⁻⁷ and a prevalence of 50 per 100 000 population based on a community registry.¹ In a well-designed consecutive series of 3781 outpatients of neurology clinics, 5.4% had a primary diagnosis of FND, and 30% had symptoms that were described as only somewhat or not at all explained by disease.⁷ Women are more frequently affected and are estimated to be 60% to 75% of the patient population, although specific presentations such as functional myoclonus or Parkinsonism appear to have similar or greater frequency in men.⁸ A crucial concern has been fear of misdiagnosis. However, in a review of 27 studies of FND (with a total study population of 1466), the frequency of misdiagnosis was consistently low (4%) after a mean of 5 years of follow-up.⁹ In a subsequent large, prospective cohort study of patients referred from primary care to specialized neurology clinics with diagnoses that were not at all or only somewhat explained by what the authors termed *organic disease*, only 4 of 1030 patients (0.4%) had been revised to (or acquired) a recognized neurological diagnosis at 18 months of follow-up.¹⁰ Thus, FNDs are common and can be accurately diagnosed by neurologists.

Phenomenology and Diagnosis

Diagnosis by *DSM-5* no longer requires identifying precipitating stressors, because these are not always found despite recent and historical stressors being more common in patients with FNDs than in healthy and clinical control participants.¹¹ Positive signs are essential in supporting a phenotype-based diagnosis that does not depend on excluding other disorders (Box 1 and Figure). However, it should be acknowledged that the specificity and sensitivity of these maneuvers may be biased by several factors, including lack of gold standards against which to compare them and unblinded assessments in most studies.¹²

Motor FND

Suggestive clinical features include sudden onset, disappearance with distraction, increase with attention, and excessive fatigue or demonstration of effort. The diagnosis is based on ascertaining specific elements of the neurological examination demonstrating inconsistency (ie, changing patterns over time with susceptibility to distraction) and/or incongruence (ie, a clinical picture incompatible with known organically determined patterns).¹³ Within this context, the examination can establish a positive rather than exclusionary diagnosis for disorders of movement (Box 1) and epileptiform disorders (Table 1).

Functional weakness is recognized by variability in severity over time and discordant performance between assessments, especially during the same examination. Functional weakness may be global or limited to one side of the body, mimicking a stroke. A pattern of giveway weakness may involve inability to rotate the head toward the paralyzed limb (with the atypical sternocleidomastoid

muscle affected),¹⁴ Hoover sign of the weak leg (Figure, A),¹⁵ and drift without pronation of the weak arm (Figure, B).¹⁶

Functional tremor is characterized by variable frequency and a characteristic response to externally cued rhythmic movements (known as entrainment test). Functional parkinsonism manifests as excessive slowness without decrement and fatigue as well as variable resistance to passive manipulation (inconsistent rigidity), with normal speed for spontaneous movements.¹⁷ Concurrent functional tremor may encourage the misdiagnosis of Parkinson disease. Functional dystonia manifests either in paroxysms or with fixed plantar flexion and inversion of the feet. Sudden onset and the presence of pain are common in functional (fixed) dystonia¹³ and rare in organic dystonia with the exception of cervical dystonia.¹⁸ Functional dystonia of the cranial region includes tonic contraction of the mouth pulled to one side, unilateral or bilateral platysma contraction, jaw and tongue deviation (Figure, C), and, when involving eye closure, elevation of the contralateral rather than ipsilateral eyebrow.^{19,20}

FND With Sensory Manifestations

Positive but less reliable diagnostic features of functional somatosensory impairments include precise midline splitting of vibration sense across the single bones of the forehead or sternum and sharply demarcated sensory loss at the groin or shoulder.²¹ Visual field testing may show a tubular (Figure, D) or missing half defect (a complete hemianopia on testing with both eyes open, contrasted with a normal visual field in the unaffected eye).²²

Persistent perceptual postural dizziness (PPPD) is a new consensus term for functional dizziness, which emerged from previous concepts including phobic postural vertigo, visual vertigo, and chronic subjective dizziness. This condition is defined as persistent disequilibrium or nonspinning dizziness provoked by upright posture, active or passive motion, and exposure to moving visual stimuli or complex visual patterns. It is usually triggered by an episode of acute dizziness, such as vestibular neuronitis or panic attack. Symptoms persist because of failure of vestibular and brain readaptation. Secondary anxiety and functional gait disorder are common accompaniments.²³

While pain is not part of *DSM-5*-defined FND, it is a common comorbidity, especially in the form of associated fibromyalgia, chronic spinal pain, complex regional pain syndrome, or migraine. As with sudden onset, pain is common in fixed dystonia but rare in organic dystonias apart from cervical dystonia.

Axial FND

Functional axial disturbances include disorders of gait and posture.^{24,25} Some gait patterns are frequently represented in patients with FNDs, such as excessive gait slowness, astasia-abasia, and knee buckling.²⁴ Excessive demonstration of effort during ambulation (also referred to as *huffing and puffing sign*) is poorly sensitive but highly specific for functional gait disorders.²⁶ Functional trunk postural abnormalities may manifest as myoclonic jerks affecting the trunk (often diagnosed as propriospinal myoclonus)²⁷ and more rarely as fixed forward-flexion of the thoracolumbar spine, which is also known as *camptocormia*.²⁵

Speech FND

Common functional speech disorders include dysfluency similar to stuttering, articulation deficits, visible demonstration of excessive

Box 1. Positive Signs in Categories of Functional Movement Disorders**Functional Poverty of Movement (Weakness and Slowness)****General Features**

Extreme slowness and fatigue
 Giveaway weakness
 Inconsistency in performance

Leg Weakness

Hoover sign
 Hip abductor sign^a
 Able to stand on toes or ankles despite weak plantarflexion or dorsiflexion on bed

Arm Weakness

Drift without pronation
 Finger abduction sign^b
 Able to remove objects from bag or put on clothes inconsistent with upper limb examination

Parkinsonism

Lack of speed or amplitude decrement on repetitive tapping (sequence effect)
 Variable resistance during passive manipulation (Gegenhalten)

Functional Excess of Movement**Tremor**

Variability in frequency
 Entrainment or full suppressibility^c
 Tonic coactivation of antagonistic muscles at tremor onset
 Pause during contralateral ballistic movements
 Whack-a-mole sign^d

Myoclonus

Entrainment or full suppressibility
 Variability in duration and or distribution of jerks or of their latency (if stimulus sensitive)
 Predominance of axial or facial jerks

Dystonia

Fixed dystonia at onset
 Variable resistance to passive manipulation

Lack of sensory trick
 Lack of overflow
 Face: tonic pulling of the lips or jaw to 1 side; closed eyelids resist retraction by examiner

Tics

Not fully stereotypical
 Interference with speech or voluntary actions
 Lack of premonitory urge
 Inability to voluntarily suppress tics

Functional Axial Manifestations**Gait**

Knee buckling
 Dragging gait with forefoot in contact with ground
 Excessive slowness or a gait similar to walking on ice

Posture

Variability of positions over time
 Inconsistent, uneconomic postures

Balance

No or controlled falls despite excessive swaying when walking
 Swaying and imbalance lessened with dual tasks

Speech

Effortful speech
 Sudden onset of dysphonia, stuttering, or dysprosody
 Foreign accent

^a Hip abductor sign is weakness of hip abduction in a paretic leg that resolves with contralateral hip abduction against resistance in the normal leg.

^b Finger abduction sign is weakness of fingers abduction that resolves with contralateral finger abduction against resistance.

^c Entrainment or ceasing of tremor to externally cued rhythmic movement or an inability to copy movement.

^d Whack-a-mole sign is the emergence or worsening of an involuntary movement in a separate body part when the initially affected body part is suppressed by someone holding it down.

effort, and prosodic abnormalities (including foreign accent), often with overlapping features.²⁸ Functional voice disorders include aphonia or dysphonia in which vocal cord or neurological pathology is absent or insufficient to account for the nature and severity of the voice disorder.

Paroxysmal FND Including Seizures/Attacks

While most FNDs fluctuate in severity over time, some are strictly episodic. At one end of the spectrum, there are patients with paroxysmal akinesia, typically evaluated for cardiogenic syncope by cardiologists. Typical positive features include long-duration attacks with closed eyes.²⁹ At the other end of paroxysmal FNDs are a variety of paroxysmal hyperkinesias (eg, tremor, dystonia, and jerks) with no apparent alteration in awareness or convulsive events with falls and variable or complete impairment of consciousness (ie, PNES).^{30,31} Helpful clinical clues distinguishing PNES from epileptic seizures are the long duration of shaking episodes (>3 minutes, placing patients

at risk of being mismanaged for status epilepticus), fluctuating course of seizures, asynchronous limb movements, pelvic thrusting, side-to-side head movements, closed eyes, ictal crying, and recall of ictal events (Table 1).^{32,33} The co-occurrence of interictal functional symptoms (eg, functional tremor) is also supportive of the interpretation of the paroxysmal movements as a manifestation of an FND. Simultaneous recording of video and physiological parameters (eg, cortical, muscle, and cardiac electrical activity, or blood pressure and oxygenation) helps exclude recognized neurological or medical conditions (such as epilepsy or syncope) to reach a documented or laboratory-supported level of diagnostic certainty for PNES.³⁴

Diagnostic Criteria

Diagnostic clinical criteria have been developed for PNES³⁴ and have high interrater reliability when using video electroencephalography,³² serving to provide a laboratory-supported definite diagnosis for PNES. In contrast, diagnostic criteria for functional movement

Figure. Clinical Signs in Selected Functional Neurological Disorders

A, Hoover sign in functional leg weakness is present if a weak hip extension is corrected when the patient flexes the contralateral hip against resistance. B, Drift without pronation sign in functional weakness is present when the affected outstretched arm, held in supination at the outset, fails to pronate when drifting. C, Fixed dystonia phenotypes expressed as fixed posturing of the jaw (unilateral deviation, often with ipsilateral platysma activation, resistant to passive manipulation), hand (with preservation of pincer function), and foot (ankle inversion with plantar flexion). D, Tubular vision in functional blindness is positive when the area of visual field defect remains unchanged despite moving away from the visual target

disorders^{13,35} may have poor interrater reliability when applied to clinically uncertain movement disorders.³⁶ The Gupta-Lang criteria for functional movement disorders introduced a laboratory-

^a In patients with PNES, events can be stereotypical in up to one-third of patients, even if the collective range of events is wider in this population.

supported, definite diagnostic category based on electrophysiological findings in functional myoclonus (which uses electromyography [EMG] and electroencephalography back-averaging for assessment of premovement potential, or *Bereitschaftspotential*) and functional tremor (surface EMG to document, among other features, entrainment, which is also termed coherence, and coactivation signs).³⁵

Probable and possible diagnostic categories for functional movement disorders are unhelpful, because they force clinicians to apply an exclusionary approach to the diagnosis by requiring investigations to exclude other disorders; a definite category permits an inclusionary examination-based diagnosis, with separate investigations only in selected cases for laboratory-supported confirmation.

Pathophysiology

Psychological Perspectives

The traditional model has been that of conversion, where psychological distress is converted into a physical symptom. The idea has existed for centuries, and Briquet provided experimental evidence³⁷ that prior experiences of abuse increased the risk of *l'hystérie*. Freud changed the focus from events to thoughts and suggested that unacceptable, usually sexual, drives were repressed from conscious awareness with the resulting psychic energy converted into physical symptoms.³⁸ Contemporary psychodynamic models emphasize that a symptom may either suppress an emotion or serve to resolve dilemmas, support important interpersonal relationships, or escape interpersonal conflicts.³⁹

While aversive experiences may increase the risk of FNDs, these cannot fully account for their development given several limitations: (1) the current lack of an explanation of the neurophysiologic mechanism of conversion, (2) the fact that similar exposures create different symptoms in different patients, (3) the long latency between exposure and FND onset in some patients (termed the *why now?* dilemma), and (4) absence of aversive events in many patients, although this may be a factor of how carefully the history is taken⁴⁰ or how comfortable the patient is about disclosing sensitive information in brief or limited medical encounters. Suggested answers to the *why now?* question include the sensitizing effect of recent events, such as trauma, medical illness, or physiological or psychophysiological events, which can form robust somatosensory experiences embedded into strong ideas and expectations about these events.⁴¹

Attentional dysregulation is a major feature in FNDs. General hierarchical information flow in the nervous system is based on the integration between bottom-up sensory information and top-down predictions about the nature of the expected sensory information. Differential weighting of the 2 streams of information leads to abnormal predictions about sensory data with abnormal body-focused attention driving abnormal perceptions or movements.⁴² Electrophysiological and psychophysical studies have provided additional support for the predictions of this model.^{42,43} The role of attention is also underscored by the suppression of symptoms with distraction, a core diagnostic feature in FNDs.⁴⁴ Used in reverse, the practice of deflecting attention away from the affected area has provided a basis for novel physiotherapies.^{45,46}

More recent psychological theories have focused more on how FND symptoms are produced rather than why they may develop. These theories have been elaborated for FNDs in general, as well as for PNES.^{42,47} The integrative cognitive model for PNES proposes that factors such as inherent responses to emotions, ideas about illness, and illness models contribute to the formation of a symptom scaffold which, especially in the context of deficient inhibition, may

be activated by arousal or internal or external stimuli perceived as threatening.⁴⁷ These models explain why the manifestations of FNDs conform to factually incorrect beliefs of what symptoms should look like and how the nervous system might go wrong.⁴⁸ One example is a tubular visual field, which is incompatible with the laws of optics. This also explains why functional symptoms may be internally inconsistent, such as the walking on ice gait, where the patient's expression of imbalance is manifested by a lurching, oscillating axial deviation on a narrow base, inconsistent with truly impaired balance function. These symptoms may be further facilitated by illness awareness, health anxiety, and excessive threat vigilance (a recognized sequelae of abusive experiences).⁴⁹ Regardless of the initiating mechanism, once the functional symptoms are formed, phobic avoidance, affective disorders, and, in time, brain plasticity may be perpetuating features.⁵⁰

Neurobiological Perspectives

Functional neuroimaging has elucidated dysfunction in FNDs at the level of brain network activity, connectivity, and specific anatomic areas of altered metabolic demand during tasks. Early research found differences between feigned and functional weakness.⁵¹ In feigned weakness, no activation was seen when participants were given the command to move. In the functional variant, normal activation within areas associated with movement preparation was accompanied by activation within the prefrontal cortex that would be unexpected during voluntary movement activation. In patients with functional tremor, dystonia, or gait abnormalities, there was hypoactivation of the supplementary motor area, a key structure involved in action selection and movement preparation, and abnormal connectivity between the supplementary motor area and limbic areas.⁵² These abnormalities, activated via negative emotional stimuli, may be associated with abnormally increased activation in areas involved in emotion recognition and self-awareness (primarily the amygdalae and cingulate gyrus⁵³) and in networks related to emotion processing and theory of mind (ability to represent mental states to understand others' intentions and predict future intentional social interaction).⁵⁴ In patients with PNES, resting-state functional magnetic resonance imaging has shown strong functional connectivity between areas involved in emotion (insula), executive control (inferior frontal gyrus and parietal cortex), and movement (precentral sulcus).⁵⁵

A deficit in the sense of agency for movements is an appealing explanation for how movements that appear voluntary in nature (because they are altered by distraction) are experienced as involuntary. Because of the relative disconnection between supplementary motor area and areas that would usually select or inhibit movement (eg, prefrontal cortex), movements occur without a normal feeling of sense of agency. Further supporting the role of impaired agency, a study of patients with functional tremor who acted as their own control participant by also voluntarily mimicking their tremor, there was hypoactivation of the temporoparietal junction, an area associated with the sense of agency for movements.⁵⁶

An Integrated Perspective

Ultimately, we need a model that integrates these neurobiological and psychological perspectives into a biopsychosocial framework. This framework should include predisposing, precipitating, and per-

Table 2. Randomized Clinical Trials of Therapeutic Interventions for Functional Neurological Disorders^a

Source	FND Type	Active Interventions	Control Treatment	Active Arm Sample Size	Control Sample Size	Main Result
Goldstein et al, ⁵⁸ 2010	PNES	12 Sessions of CBT modified for PNES, plus SMC	SMC ^b alone	33	33	The active arm had lower PNES frequency at end of treatment; differences were nonsignificant at 6 mo and with respect to 3-mo seizure freedom.
LaFrance et al, ⁵⁹ 2014	PNES	12 CBT-informed sessions of psychotherapy alone; 12 CBT-informed sessions of psychotherapy and flexible-dose sertraline; Flexible-dose sertraline alone	SMC ^b alone	Psychotherapy: 9; Psychotherapy and sertraline: 10; Sertraline: 9	10	The psychotherapy group had 51.4% lower PNES frequency; the psychotherapy and sertraline group had 59.3% lower PNES frequency; those receiving sertraline only had a nonsignificant finding of 26.5% lower PNES; and the control group had a nonsignificant finding of 33.8% lower PNES.
Nielsen et al, ⁴⁵ 2017	Functional motor disorder	Specialized physical therapy for functional motor disorder (5-d outpatient program) ⁶⁰	Generic neurophysiotherapy	30	30	The active arm had 72% rated symptoms improvement at 6 mo and SF-36 physical function adjusted mean difference of 19.8 (vs the control group). In the control arm, rated symptoms improved 18% at 6 mo.
Jordbru et al, ⁶¹ 2014	Functional motor disorder	Inpatient adapted physical therapy	Delayed start design	30	30	The active arm had a mean difference on functional independence measure 8.4 points greater than control arm (scale 18-125; sustained at 1 y).
Moene et al, ⁶² 2002	Functional motor disorder	Eight 1-h sessions of manualized hypnosis, plus inpatient group psychotherapy and other multidisciplinary team input	8 Nonspecific 1-h therapy sessions, plus inpatient group psychotherapy and other multidisciplinary team input	24	21	The study found overall improvement in all outcome measures in both groups. No additional effect on outcome in the active arm.
Moene et al, ⁶³ 2003	Functional motor disorder	Outpatient manualized hypnosis (10 sessions over 3 mo)	Waiting list	20	25	There was a greater improvement on Video Rating Scale for Motor Conversion Symptoms in the active arm.
Dalocchio et al, ⁶⁴ 2016	Functional motor disorder	CBT, plus adjunctive physical activity; CBT alone	SMC ^b	CBT and activity: 15; CBT alone: 14	8	In both active arms, there was significant Psychogenic Movement Disorder Rating Scale improvement; no differences were observed between active groups, and no improvement in the control arm.
Sharpe et al, ⁶⁵ 2011	Mixed FND	CBT-based guided self-help in 4 30-min sessions, plus SMC ^b	SMC ^b	64	63	The active arm had greater improvement on self-rated 5-point CGI at 3 mo than the control group.
Hubschmid et al, ⁶⁶ 2015	Functional motor disorder or PNES	4-6 Sessions of interdisciplinary psychotherapeutic intervention, plus 2 sessions with a neurologist and psychiatrist	SMC ^b	11	12	The active arm had greater improvement on SDQ-20, CGI, mental health scores on SF-36, and depression at 12 mo than the control group.

petuating factors involving genetics, neural networks, temperament, cognition, emotion, and environmental influences.⁵⁷

Treatment

Treatment of FNDs is a process that starts with explaining the diagnosis in a way that helps the patient understand and gain confidence in it. This in turn enhances the odds of adherence to and success from therapeutic strategies. Although randomized clinical trial evidence is limited, promising data are emerging from cohort and pilot randomized studies to support specific treatments (Table 2). How best to select patients for specific treatments and predictors of response are important knowledge gaps, but certain general principles are known to apply (Box 2).

Delivery of Diagnosis

A critical first step in increasing favorable outcomes is the discussion of the diagnosis with the patient, encompassing these critical

points: (1) there is an established diagnosis; (2) in most cases, the diagnosis can be made definitively with a neurological examination, rather than as a diagnosis of exclusion; and (3) the disorder is potentially reversible with treatment. The effectiveness of the diagnostic delivery can be helped by disclosing to patients how the diagnosis was made, including the specific features on examination that make it clinically definite, when such level of certainty can be achieved (eg, demonstration of the Hoover sign or tremor entrainment).⁶⁷ Success in this step ensures that the patient leaves with (1) a validation of the neurological symptoms and/or disability, (2) confidence in the diagnosis, preventing the need to seek alternative medical opinions, (3) a sense of partnership with the neurologist, and (4) an understanding of the rationale for tailored multidisciplinary management, which may include psychological interventions.

Functional Overlay

It is important to note the possibility of other concurrent or future medical comorbidities (eg, comorbid epilepsy or Parkinson

Box 2. General Treatment Principles of Therapy for Functional Neurological Disorders

General Principles

Diagnosis should be established prior to starting therapy and clearly communicated to the patient within a biopsychosocial framework.

Encourage transparency, especially regarding positive diagnostic features.

Explore and address unhelpful illness beliefs and behaviors.

Ensure that the patient understands potential for reversibility and is motivated to change.

Foster independence and self-management during treatment.

Involve the family and caregivers in treatment.

Functional Movement Disorder–Specific Principles

Establish the treatment goal of relearning normal motor control.

Motor retraining begins by establishing elementary movements (eg, weight-shifting) and consecutively adding more complex movements.

Visual feedback during motor relearning from mirrors and video can be helpful.

Emphasis is placed on the quality of movement instead of the quantity.

Avoid excessive attention to abnormal movements.

Treatment adjuncts may enhance movement relearning: treadmill training, electrical stimulation, electromyography biofeedback, and transcranial magnetic stimulation.

Nonepileptic Seizure–Specific Principles

Learn techniques to avert episodes, if there are warning symptoms.

Foster cognitive awareness of triggers when these are present.

Develop a self-management and relapse plan.

Learn to challenge safety or avoidance behaviors around episodes.

disease).^{68,69} A properly explained diagnosis should not alienate patients from requesting a reevaluation if they develop new symptoms. This also mandates a mature response from health care professionals, who should not be dismissive (ie, not all manifestations are solely because of a patient's FND). Treatment options for FNDs need to reflect the diversity of symptom phenotypes as well as the heterogeneity and comorbidity within the patient population; there is no one-size-fits-all approach.

Psychological Treatments of FND

Psychological interventions have traditionally been considered the treatment of choice. Studies of psychological therapies have been undertaken in subpopulations with FNDs, with particularly promising results for disorder-adapted cognitive behavioral therapy for PNES and functional movement disorders, and for multimodal cognitive behavioral–informed psychotherapy for PNES, as well as cognitive behavioral therapy–oriented self-management and interdisciplinary psychodynamic interpersonal therapy for a wider range of FNDs (Table 2).^{58,59,62–66} Cognitive behavioral therapy is a structured, time-limited therapy that helps patients identify how thinking affects emotional states or specific behaviors. Cognitive behavioral therapy and other psychotherapies (designed for PNES) include

components such as education, skills in gaining control of seizures, recognizing triggers, changing cognitions and behaviors associated with seizures, and widening therapy to other aspects of interpersonal functioning.

Physical Treatment of FND

Recently, a greater role for physical therapy has been recognized when motor symptoms predominate (Table 2).^{45,61,70,71} However, while many such studies focus on the physical treatment of FNDs, most successful programs incorporate psychotherapeutic modalities (eg, cognitive behavioral, psychoeducation, stress reduction techniques), underscoring the importance of addressing the brain and behavioral elements. Motor rehabilitation strategies aim to help the patient to establish normal control of movement through physiotherapy, occupational therapy or speech therapy, informed by an understanding of FNDs (Box).

Motor retraining begins with establishing basic movement patterns (eg, weight-shifting), and the complexity of movement is sequentially increased toward normal movement patterns. The focus lies on function and automatic movement (eg, walking) rather than specific impairments (eg, weakness) and controlled movement, such as strengthening exercises. Reduced symptom severity with distraction can be used as part of motor retraining by redirecting the patient's focus of attention toward the goal of the movement (eg, transferring from bed to chair) and away from the individual components of the movement (eg, knee extension). Encouraging movements that are initiated more automatically, such as rhythmical weight-shifting, or novel movement, such as walking backward, can trigger normal movement patterns. Unhelpful cognitions (eg, thinking "my nerves are damaged") and behaviors (eg, acting as though moving could cause more damage) should be addressed as part of the treatment to integrate important aspects of psychological treatment.⁶⁰ Chronic pain and fatigue are common comorbidities in FNDs and, when these are present, patients may benefit from specific interventions to address these issues, and treatment approach may need to be adapted (eg, lower intensity or domiciliary treatment). Outpatient interventions with a physical or neurorehabilitation focus may be beneficial for patients with less severe symptoms, and treatment success can sometimes be achieved in short periods.^{45,61,70}

Other Treatments

Comorbid depression and anxiety as well as pain may be treated pharmacologically. However, treatments directed at symptoms (eg, antitremor medications) are not appropriate. Furthermore, favorable responses to any pharmacological treatment can occur because of positive effects on mood, coexisting disease, or placebo response. Multidisciplinary treatment for severely affected patients has shown promise in single-center studies. Many non-pharmacological interventions have been used in single cases or small case-series, as ancillary treatments for FNDs. These include transcutaneous electrical stimulation, transcranial magnetic stimulation, and therapeutic sedation with propofol.⁷² The mechanism of action of central and peripheral neuromodulation treatments is uncertain, although this is likely to be mediated by a cognitive-behavioral effect rather than by a modification of cortical excitability.⁷³

Prognosis

Partly because of underrecognition or poorly delivered FND diagnoses and a lack of availability of knowledgeable therapists, the prognosis of FND remains collectively poor, with disability persisting or even worsening over time. Many patients with good understanding and acceptance of the diagnosis continue to have severe symptoms despite treatment. Ongoing or anticipated litigation or disability proceedings may act as conflicts of interest, affecting the likelihood of success in some patients. Consistent negative predictors include long duration of symptoms (with accrual of severe disability and secondary gain) before diagnosis and personality disorders, whereas good outcomes are associated with young age and early diagnosis.^{72,74} Even in unfavorable scenarios, treatment of comorbidities and limitation of iatrogenic harm are important management strategies, which can be accomplished if the diagnosis is accurately conveyed to the referring physician and the patient's other health care clinicians. There are currently no established clinical fac-

tors or ancillary testing to guide which patients may benefit from which treatment modalities and over what period.

Conclusions

Functional neurological disorders are common and disabling but potentially reversible. A positive or inclusionary diagnosis can be made with a high level of certainty. Treatment includes psychological interventions, such as cognitive-behavioral therapy, behavioral therapy, or psychodynamic therapy and, for functional motor disorder, rehabilitation strategies. While the level of evidence has increased for some of these interventions, further research is needed to determine the dose and duration of various approaches, the value of combination and multidisciplinary therapy, and the appropriate therapeutic modality for each patient. Therapeutic success hinges on diagnostic delivery that validates the patient's symptoms and disability and allows full understanding and acceptance of the diagnosis by the patient.

ARTICLE INFORMATION

Accepted for Publication: March 19, 2018.

Published Online: June 4, 2018.

doi:10.1001/jamaneurol.2018.1264

Author Affiliations: University of Cincinnati Gardner Neuroscience Institute, Gardner Family Center for Parkinson's Disease and Movement Disorders, Department of Neurology, University of Cincinnati, Cincinnati, Ohio. (Espay); Department of Neurology, University Hospital Inselspital, Bern, Switzerland (Aybek); Neuropsychiatry, Centre for Clinical Brain Studies, University of Edinburgh, Edinburgh, United Kingdom (Carson); Motor Control and Movement Disorders Group, Institute of Molecular and Clinical Sciences, St George's University of London, London, United Kingdom (Edwards, Nielsen, Morgante); Department of Psychology, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom (Goldstein); Human Motor Control Section, National Institute of Neurological Disorders and Stroke, National Institutes of Health, Bethesda, Maryland (Hallett); Department of Neurology, University of Louisville, Louisville, Kentucky (LaFaver); Department of Psychiatry, Alpert Medical School of Brown University, Providence, Rhode Island (LaFrance); Department of Neurology, Alpert Medical School of Brown University, Providence, Rhode Island (LaFrance); Morton and Gloria Shulman Movement Disorders Centre, Toronto Western Hospital and Edmond J. Safra Program in Parkinson Disease, University of Toronto, Toronto, Ontario, Canada (Lang); Section of Cognitive Neuropsychiatry, Department of Psychosis Studies, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom (Nicholson); Academic Neurology Unit, University of Sheffield, Royal Hallamshire Hospital, Sheffield, United Kingdom (Reuber); Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom (Voon); Centre for Clinical Brain Sciences, University of Edinburgh, Western General Hospital, Edinburgh, United Kingdom. (Stone); Department of Clinical and Experimental Medicine, University of Messina, Messina, Italy (Morgante).

Author Contributions: Dr Espay had full access to all of the data in the study and takes responsibility for the integrity of the data and the accuracy of the data analysis.

Study concept and design: Espay, Carson, Edwards, Goldstein, LaFaver, LaFrance, Jr, Nicholson, Nielsen, Reuber, Voon, Stone, Morgante.

Acquisition, analysis, or interpretation of data: Espay, Aybek, Edwards, Hallett, Lang, Reuber.

Drafting of the manuscript: Espay, Aybek, Carson, Edwards, Goldstein, Hallett, LaFaver, LaFrance, Jr, Nicholson, Nielsen, Reuber, Voon, Stone, Morgante.

Critical revision of the manuscript for important intellectual content: Aybek, Edwards, Goldstein, Hallett, LaFaver, LaFrance, Jr, Lang, Nielsen, Reuber, Voon, Stone, Morgante.

Administrative, technical, or material support: Nicholson.

Study supervision: LaFrance, Jr, Lang, Stone, Morgante.

Conflict of Interest Disclosures: Dr Espay is supported by the National Institutes of Health and has received grant support from CleveMed/Great Lakes Neurotechnologies, Davis Phinney Foundation, and the Michael J Fox Foundation; personal compensation as a consultant or scientific advisory board member for Solvay, Abbott, Chelsea Therapeutics, TEVA, Impax, Merz, Lundbeck, and Eli Lilly; honoraria from TEVA, UCB, the American Academy of Neurology, and the Movement Disorders Society; and publishing royalties from Lippincott Williams & Wilkins, Cambridge University Press, and Springer. Dr Aybek is supported by a Swiss National Foundation Ambizione Grant (grant PZ00P3-147997). Dr Carson acknowledges submitting paid testimony in court actions on a range of neuropsychiatric topics and receiving payment as editor of *Journal of Neurology, Neurosurgery, and Psychiatry* and royalties from BMJ press and Elsevier for books. Dr Edwards has received research funding from the Medical Research Council, National Institute for Health Research, and the Guarantors of Brain; honoraria from Merz Pharma, TEVA, and UCB; and publishing royalties from Oxford University Press. Dr Goldstein has received research funding from the National

Institute of Health Research and publishing royalties from Wiley and Routledge. Dr Hallett serves as Chair of the Medical Advisory Board for and may receive honoraria and funding for travel from the Neurotoxin Institute. He might accrue revenue on US patent #6,780,413 B2 (issued August 24, 2004): Immunotoxin (MAB-Ricin) for the treatment of focal movement disorders, and US patent #7,407,478 (issued August 5, 2008): Coil for Magnetic Stimulation and methods for using the same (H-coil); in relation to the latter, he has received license fee payments from the National Institutes of Health (from Brainsway) for licensing of this patent. He is on the Medical Advisory Board of Cala Health. He is on the editorial board of approximately 20 journals, and received royalties and/or honoraria from publishing from Cambridge University Press, Oxford University Press, and Elsevier. Dr Hallett's research at the National Institutes of Health is largely supported by the National Institutes of Health Intramural Program. Supplemental research funds have been granted by Merz for treatment studies of focal hand dystonia, Allergan for studies of methods to inject botulinum toxins, Medtronic Inc for a study of deep brain stimulation for dystonia, and Cala Health for studies of a device to suppress tremor. Dr LaFaver has received honoraria from Pfizer, Teva, the American Academy of Neurology, and the Movement Disorders Society and is on the medical advisory board for FND Hope, a patient organization for functional neurological disorders. Dr LaFrance has served on the editorial boards of *Epilepsia*, *Epilepsy & Behavior*, *Journal of Neuropsychiatry and Clinical Neurosciences* and *Journal of Neurology, Neurosurgery and Psychiatry*; receives editor's royalties from the publication of *Gates and Rowan's Nonepileptic Seizures*, 3rd ed. (Cambridge University Press, 2010) and 4th ed. (2018); author's royalties for *Taking Control of Your Seizures: Workbook and Therapist Guide* (Oxford University Press, 2015); has received research support from the National Institutes of Health/ National Institute of Neurological Disorders and Stroke (grant 5K23NS45902), Rhode Island Hospital, the American Epilepsy Society, the Epilepsy Foundation, Brown University, the Siravo

Foundation, and the Department of Defense (grant W81XWH-17-1-0619); serves on the Epilepsy Foundation Professional Advisory Board; has received honoraria for the American Academy of Neurology Annual Course; has served as a clinic development consultant at University of Colorado Denver, Cleveland Clinic, Spectrum Health, and Emory University; and has provided medicolegal expert testimony. Dr Lang has served as an advisor for AbbVie, Allon Therapeutics, Avanir Pharmaceuticals, Biogen Idec, Boehringer Ingelheim, Bristol-Myers Squibb, Ceregene, Cipla, Intekrin, Lilly, Medtronic, Merck, Novartis, NeuroPhage Pharmaceuticals, Teva, and UCB; received honoraria from Medtronic, Teva, UCB, and AbbVie; received grants from Brain Canada, the Canadian Institutes of Health Research, the Edmond J. Safra Philanthropic Foundation, The Michael J Fox Foundation, the Ontario Brain Institute, National Parkinson Foundation, Parkinson Society Canada, Physicians Services Incorporated, Tourette Syndrome Association, W Garfield Weston Foundation; received publishing royalties from Saunders, Wiley-Blackwell, Johns Hopkins Press, and Cambridge University Press; and has served as an expert witness in cases related to the welding industry. Dr Nicholson receives research funding from the National Institute for Health Research. Dr Nielsen receives research funding from the National Institute for Health Research. Dr Reuber receives payment as Editor in Chief of *Seizure: European Journal of Epilepsy*; royalties from Oxford University Press; an unrestricted research grant from UCB; and speaker fees from Eisai, Livanova, and UCB. Dr Voon is a Medical Research Council Senior Fellow (grant MR/P008747/1). Dr Stone receives royalties from UpToDate Inc, BMJ Publications, and Elsevier, and acknowledges paid testimony in court in relation to functional neurologic disorders. He is supported by NHS Scotland Career Fellowship and runs the free website <https://www.neurosymptoms.org/> for patients with functional neurologic disorders. Dr Morgante has received honoraria as a Consultant and Advisory Board member from Medtronic, UCB, and Chiesi. She has received honoraria for speaking from UCB Pharma, Medtronic, Zambon, Chiesi, and Abbvie. She serves on the editorial boards of *Movement Disorders Clinical Practice* and *Frontiers in Movement Disorders*. She receives royalties from the publication of *Disorders of Movement* (Springer, 2016).

Funding/Support: This article presents independent research part-funded by the National Institute for Health Research, Maudsley Biomedical Research Centre at the South London, and Maudsley National Health Service Foundation Trust and King's College London.

Role of the Funder/Sponsor: The funders had no role in the design and conduct of the study; collection, management, analysis, and interpretation of the data; preparation, review, or approval of the manuscript; and decision to submit the manuscript for publication.

Disclaimer: The views expressed are those of the author and not necessarily those of the National Health Service, the National Institute of Health Research, or the Department of Health and Human Services.
